Frost Survival of Plants Akira Sakai, Walter Larcher, 2012-12-06 Low temperature represents together with drought and salt stress one of the most important environmental constraints limiting the productivity and the distribution of plants on the Earth Winter survival in particular is a highly complex phenomenon with regards to both stress factors and stress responses The danger from winter cold is the result not only of its primary effect i.e. the formation of ice in plant tissues additional threats are presented by the freezing of water in and on the ground and by the load and duration of the snow cover In recent years a number of books and reviews on the subject of chilling and frost resistance in plants have appeared all of these publications however concentrate principally on the mechanisms of injury and resistance to freezing at the cellular or molecular level We are convinced that analysis of the ultrastructural and biochemical alterations in the cell and particularly in the plasma membrane during freezing is the key to understanding the limits of frost resistance and the mechanisms of cold acclimation This is undoubtedly the immediate task facing those of us engaged in resistance research It is nevertheless our opinion that in addition to understanding the basic physiological events we should be careful not to overlook the importance of the comparative aspects of the freezing processes the components of stress avoidance and tolerance and the specific levels of resistance
