Why a Special Issue on Prenatal Substance Exposure?

In the United States, exposure to maternal use of drugs and alcohol, pre- and/or postnatally, is one of the most common risk factors associated with children's negative behavioral and developmental outcomes. Despite evidence linking alcohol and tobacco to fetal damage and warnings from public health campaigns, currently, at least 10% of women drink alcohol during pregnancy (Centers for Disease Control and Prevention, 2004) and 11% smoke cigarettes (Martin, Kochanek, Strobino, Guyer, & MacDorman, 2005). Although these reported rates have declined in recent years, they may not reflect exposure early in the pregnancy before women know they are pregnant. For instance, recently the Centers for Disease Control and Prevention (2004) reported that over 50% of women of childbearing age who were not using birth control drank alcohol and were, therefore, at risk for pregnancy complicated by fetal risk. Maternal substance use also includes marijuana, "hard drugs" (heroin, cocaine, and methamphetamines), and prescription medications, either through medical advice or misuse. As evidence has accumulated about the teratogenic risk associated with such use, professionals and the public have become aware of the need to understand the impact on pregnancy outcomes and children's development. Initial concerns regarding the presumed, but undocumented, effects of substance exposure on children's development have given way to a more balanced approach that examines how substances interact with environmental factors to influence children's development. Information from current studies demonstrates

the importance of developing strategies to promote the health and development of exposed children, to implement effective prevention programs, and to avoid the unnecessary anxiety that can stigmatize mothers and children.

The knowledge base regarding the effects of prenatal exposure to substances of abuse is growing, often in response to interest by scientists and the support available from federal funding sources. Research on the effects of prenatal exposure to substances of abuse has occurred in response to the scientific awareness of the dangers to children, as when fetal alcohol syndrome was first described in 1973 (Jones and Smith, 1973), and to public health concerns regarding "epidemics" of drug use, such as heroin in the 1960s, and cocaine and crack in the late 1980s and early 1990s. Currently, there is a great deal of attention being paid to the effects of pre- and postnatal exposure to tobacco and to methamphetamines.

Much of the recent research on the effects of prenatal drug exposure has been conducted among young children exposed to cocaine prenatally. The emerging findings on performance during the school-age years have been mixed. Some investigators have found that prenatal cocaine exposure is not associated with cognitive performance (Chasnoff et al., 1998; Richardson et al., 1996), play behavior (Accornero, Morrow, Bandstra, Johnson, & Anthony et al., 2002), academic achievement (Richardson et al., 1996), attention or teacher-rated classroom behavior (Richardson et al., 1996). However, others have found that prenatal cocaine exposure may be associated with behavior problems (Chasnoff et al., 1998), task persistence and attention problems (Bandstra, Morrow, Anthony, Accornero, & Fried, 2001), and language performance (Bandstra,
