Erythropoietin In Clinical Applications:

Erythropoietin: From Molecular Structure to Clinical Application C. A. Baldamus, K. M. Koch, P. Scigalla, L. Wiczorek, 1989-10-18 **Clinical Applications of Cytokines** Joost J. Oppenheim, Jeffrey L. Rossio, A. J. H. Gearing, 1993

The driving force for research on cytokines has always been their clinical promise. Their biological properties suggested a key role in hematopoiesis, immunity, tumor genesis, hemostasis, vascularization, repair of connective tissues, and integration of the immune system with the neuroendocrine system. Animal studies have shown that cytokines could be used as effective biotherapeutics with easily manageable and reversible toxicities. Clinical trials have confirmed these findings, culminating in the licensing of a number of the cytokines such as interferon alpha, interferon gamma, interleukin 2, erythropoietin, granulocyte colony stimulating factor, and granulocyte macrophage colony stimulating factor. Many other cytokines are in clinical trials. This is the first comprehensive volume on the cytokines, written primarily from a medical perspective. After presenting background information about the structure, production, assays, and systemic effects of cytokines and their receptors, it is organized around diseases and organ systems. Infectious diseases, autoimmunity, immunodeficiency states, defective hematopoiesis, allergies, injury, repair, cancer, vascular and skin diseases, and neurological disorders are all covered. This work reviews the role that cytokines play in the pathogenesis, diagnosis, and therapy of each disease. The authors assess both the current state of the art and the potential for future applications.

Clinical Applications of Cytokines and Growth Factors John R. Wingard, George D. Demetri, 2012-12-06

The hematopoietic system plays roles that are crucial for survival of the host: delivery of oxygen to tissues, arrest of accidental blood leaking from blood vessels, and fending off of invading microbes by humoral, cell-mediated, and phagocytic immunity. The activity of the hematopoietic system is staggering: daily, a normal adult produces approximately 2.5 billion erythrocytes, 2.5 billion platelets, and 1 billion granulocytes per kilogram of body weight. This production is adjusted in a timely fashion to changes in actual needs and can vary from nearly none to many times the normal rate depending on needs, which vary from day to day or even minute to minute. In response to a variety of stimuli, the cellular components of the blood are promptly increased or decreased in production to maintain appropriate numbers to optimally protect the host from hypoxia, infection, and hemorrhage. How does this all happen and happen without over or under responding? There has been extraordinary growth in our understanding of hematopoiesis over the last two decades. Occupying center stage is the pluripotent stem cell and its progeny. Hematopoietic stem cells have been characterized by their capacity for self-renewal and their ability to proliferate and differentiate along multiple lineages. Few in number, the stem cell gives rise to all circulating neutrophils, erythrocytes, lymphoid cells, and platelets. In hematopoietic transplantation, the stem cell is capable of restoring long-term hematopoiesis in a lethally irradiated host.
