

# Mechanisms of eye-specific visual circuit development

Andrew D Huberman

Eye-specific visual connections are a prominent model system for exploring how precise circuits develop in the CNS and, in particular, for addressing the role of neural activity in synapse elimination and axon refinement. Recent experiments have identified the features of spontaneous retinal activity that mediate eye-specific retinogeniculate segregation, the synaptic events associated with this process, and the importance of axon guidance cues for organizing the overall layout of eye-specific maps. The classic model of ocular dominance column development, in which spontaneous retinal activity plays a crucial role, has also gained new support. Although many outstanding questions remain, the mechanisms that instruct eye-specific circuit development are becoming clear.

## Introduction

What mechanisms induce development of precise CNS circuitry? A classic model circuit for investigating this question is eye-specific visual connections: axons carrying visual information for the left and right eyes are segregated into non-overlapping domains in the lateral geniculate nucleus (LGN) and into ocular dominance columns (ODCs) in the visual cortex. The cellular events involved in eye-specific retinogeniculate refinement are well characterized: after an initial overlap phase, axons from the two eyes segregate by elaborating synapses and axon terminals in the same-eye territory and by eliminating synapses and axon terminals in opposite-eye territory [1,2]. Spontaneous retinal activity is known to be required for segregation to occur [3], but several important questions have remained unanswered: which features of spontaneous retinal activity are instructive for eye-specific segregation? What are the molecular mechanisms for eliminating weaker synapses and maintaining strong ones? What factors dictate the

overall layout of eye-specific maps? Similar questions exist regarding ODC development as well. In the past decade, however, even the basic cellular events associated with ODC development have become controversial as several high profile studies [4,5] challenged the idea that ODCs are sculpted by early retinal activity. Here, I review recent advances in our understanding of retinogeniculate and ODC development, and I suggest experiments that could further elucidate how these circuits form.

## The role of patterned retinal activity in eye-specific retinogeniculate segregation

Neural activity mediates development of eye-specific retinogeniculate projections through competitive interactions involving the relative levels of retinal ganglion cell (RGC) spiking in the two eyes [3,6]. Hebbian models predict, however, that correlated firing — and not simply activity levels per se — of neighboring RGCs is crucial for eye-specific segregation [7]. In theory, retinal waves [8] induce patterns of RGC spiking optimal for Hebbian-based axonal refinement but, surprisingly, the first experiments to perturb retinal waves did not observe any accompanying disruptions to eye-specific segregation in the LGN [9]. Moreover, some mutant mice with altered retinal waves exhibit severe eye-specific retinogeniculate defects [10], and yet pharmacologically inducing waves in these mutants does not rescue segregation [11]. Thus, to elucidate which aspects of spontaneous retinal activity instruct eye-specific segregation, Feller and colleagues [12\*\*] undertook a systematic analysis of RGC spiking patterns in different strains of mutant mice, each with differently altered retinal waves but with varying degrees of eye-specific segregation in the LGN. They found that high frequency correlated bursting ( $>10$  Hz) of neighboring RGCs is a key parameter required for eye-specific segregation. They also found that the precise time-window for RGC firing is not crucial for segregation, provided that the degree of correlated firing among closely spaced RGCs remains relatively higher than the degree of correlation among distant RGCs. Their results suggest why in previous experiments where retinal waves were disrupted, the anticipated defects in retinogeniculate refinement were not observed [6,9]. They also suggest which types of synaptic plasticity can (and cannot) drive segregation. For instance, because low frequency ( $\sim 1$  Hz) RGC firing is not related to segregation [12\*\*], it is unlikely that typical forms of long-term depression (LTD) mediate synaptic elimination in this system. By contrast, the importance of high frequency RGC bursts suggests that bursts trigger plasticity mechanisms that both stabilize same-eye inputs and eliminate opposite-eye inputs onto single LGN cells (i.e. heterosynaptic depression). Cohen, Philip Salapatek, 2013-09-24 Infant Perception From Sensation to Cognition Volume I Basic Visual Processes focuses on the study and programmatic investigations of infant perception examining early sensory perceptual and cognitive systems This book is divided into five chapters Chapter 1 analyzes the major physiological and behavioral techniques used to measure infant vision Each technique is critically evaluated in terms of the method employed type of data that can be obtained and anatomy of the visual system The neuronal model to explain developmental changes and techniques used to assess infant visual preferences for patterns varying in amount of contour are discussed in Chapter 2 Chapter 3 demonstrates the value of the corneal reflection technique for the study of infant attention and visual scanning patterns while Chapter 4 examines the developmental changes and individual differences in early pattern perception The last chapter concentrates on the evidence of infant visual preferences for novelty and on the implications of such evidence for models of early recognition memory This publication is a good reference for pediatricians and clinicians concerned with infant perception      **The Visual Process** Hugh Davson, 2014-05-12 The Eye Volume 2 The Visual Process is a compendium of papers that describes the physiology of the eye particularly the visual functions the photobiology of the visual process and the visual pathway One paper describes the light stimuli used in physiological experiments concerning vision in terms of their spectral energy distribution particularly the amounts of light absorbed by the photosensitive substances contained in the retinal receptors Another paper explains the mosaic like arrangement of the receptors and the variations of this mosaic in the different regions of the retina including the Purkinje phenomenon which can cause errors in visual measurements One paper examines the directional properties of the rods at long wavelengths and the theory of the Stiles Crawford effect Other papers investigate the limits of the visible spectrum the scotopic luminous efficiency theories of
