

Below Mach 1

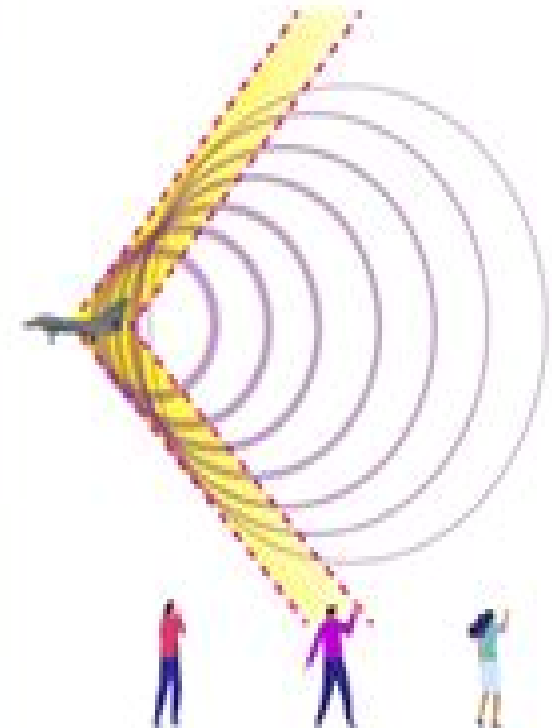

An aircraft in flight creates a series of pressure waves that travel outward in all directions and perceived as sound

Mach 1

The faster the aircraft moves, the more compressed the waves become.

Above Mach 1

Eventually the waves merge into a shock wave. A person on the ground hears a boom when the shock wave crosses his location.

plaster and brick A literature survey was performed to identify existing models suitable for an environmental planner to use for assessing the impact of supersonic flights on conventional structures A model developed by Hershey and Higgins was identified as the most nearly suitable model As a result of an extensive sensitivity analysis of this model a number of enhancements to the model were developed Finally the revised model was packaged to facilitate the use by an environmental planner A comparison of the existing U S Air Force methodology and the mean damage estimates produced by the new approach shows that the existing method usually produces higher loss estimates although sometimes the loss estimates are comparable The new method offers the advantage of quantifying the degree of conservatism in damage estimates and extending it from window panes to include other vulnerable materials Keywords Sonic booms Structural response model Structural effects Conventional structures Damage to windows **Noise Control** United States.
