Computer Model for Geothermal Plant Scaling and Corrosion Analyses, 1976 It is generally recognized that corrosion and scaling problems could seriously affect the operation and electric power production from a geothermal power plant The Electric Power Research Institute EPRI has sponsored a study at Battelle Northwest BNW to develop a brine chemistry data base and analytical tools to analyze how corrosion and scaling affect the degradation of the power output of a geothermal plant The GEOSCALE computer model is a steady state thermal hydraulics code that describes the process parameters of the power plant At present the multistage flash and binary cycle plants are being analyzed Initially the code computes the power output from a given geothermal brine flow and provides flow rates temperature velocities at points from the bottom of the production wells through the plant to the waste injection system Based on the starting brine chemistry and these process parameters corrosion and scaling rates will be estimated at points throughout the system The amount of scale formation in a time interval will be calculated and the impact on brine flows and heat transfer calculated resulting in a new set of plant process parameters for the next iteration The iterations continue until some portion of the plant is degraded to a process limit or a plant life of 20 to 30 years is reached Obviously the most difficult part of this analysis is the lack of valid analytical expressions and supporting rate data to calculate scaling The general approach to the scaling rate equations is that the rate of buildup is proportional to the degree of insolubility of a mineral minus the rate of mechanical removal They are very interested in all current scaling work that could help in providing scaling kinetics data related to process parameters so they can test these analytical expressions The program includes a computer subroutine for calculating mineral insolubilities as brines cool a chemical and structural analysis of several actual scale samples and a laboratory experimental program to examine scaling kinetics **A Study of Brine Treatment** Sidney L. Technical Information Center, 1976 **Study of Treatment Methods for Geothermal Fluids. [Review of Methods Used to Control Scaling and Corrosion, Current Research Programs, and Recommendations]**. , 1977 A study of methodology used to control geothermal scaling and corrosion is presented The information used for this study was screened from the geothermal oil and gas wastewater disposal and boiler water treatment industries This information was evaluated and the current state of knowledge and methodology concerning the treatment of geothermal brines to control scaling and corrosion in geothermal electric power production was assessed Currently geothermal scale in pipes and wells is removed by physical or chemical methods There is a growing effort to develop methods for controlling scale formation for both fresh and spent brines including pH adjustment and application of an electrical potential for fresh fluids and coagulation to treat spent fluids Current methods of corrosion control center around planned replacement of piping and other plant components with efforts focused primarily on development of materials with improved corrosion resistance Recommendations for additional work include the following 1 chemical and physical characterization of brine and scale compositions 2 basic data on the mechanism of scale formation and the effects of inhibitors 3 development of instrumentation to monitor geothermal brine constituents 4 correlation of laboratory results with field test data and 5 screening of currently available commercial inhibitors for application to geothermal brines Selected Water Resources Abstracts , 1978
